1 Project Description

The following report details the findings of the offsite drainage hydrology and hydraulic impact study of the proposed Oakhill Parkway (US 290/ SH 71) improvement project in southwest Austin, Travis County, Texas. These impacts include the increased impervious area, the proposed offsite detention evaluation, diverted flow from the Kincheon Branch sub-basin, the hydraulic evaluation of 4 major stream crossings, overbank impacts due to encroachment of the proposed grade and elevated roadways, and the proposed hydraulic mitigation efforts deemed necessary, such as berms and overbank grading.

H & H Resources, Inc. (HHR) produced two previous technical memos as part of this overall drainage study. The first memo from February 5, 2014 (Feb-2014 HHR), outlined the initial hydrologic impacts drawing information from a previous feasibility study performed by HDR Engineering, Inc. (HDR) in 2007 (SH 71/US 290 Offsite Detention Feasibility Study). The Feb-2014 HHR memo assessed the previous study's findings and adjusted and expanded on those recommendations accordingly. The second technical memo produced by HHR on June 3 2016 (June-2014 HHR) outlined the initial hydraulic analysis and results. Specifically, it analyzed the impacts of the proposed detention scenarios presented in the Feb-2014 HHR memo, corresponding peak flow reductions in Williamson Creek in the project area, and the performance of the initial bridge layouts available at that time. The following report will combine the findings from these previous technical memos, outline the updated hydrologic and hydraulic modeling of the latest layouts and alignments, and review final results.

1.1 Project Location

The proposed project area extends along US 290 from Circle Drive to Joe Tanner Lane, and along SH 71 from Silvermine Drive to the interchange with US 290. The existing US 290 highway consists of four main lanes with a continuous center turn lane and runs along the south bank of Williamson Creek between the SH 71 interchange until it crosses the creek just east of McCarty Lane. The bulk of the project impact will occur at this section along Williamson Creek and will impact, expand, or replace four existing creek crossings structures.

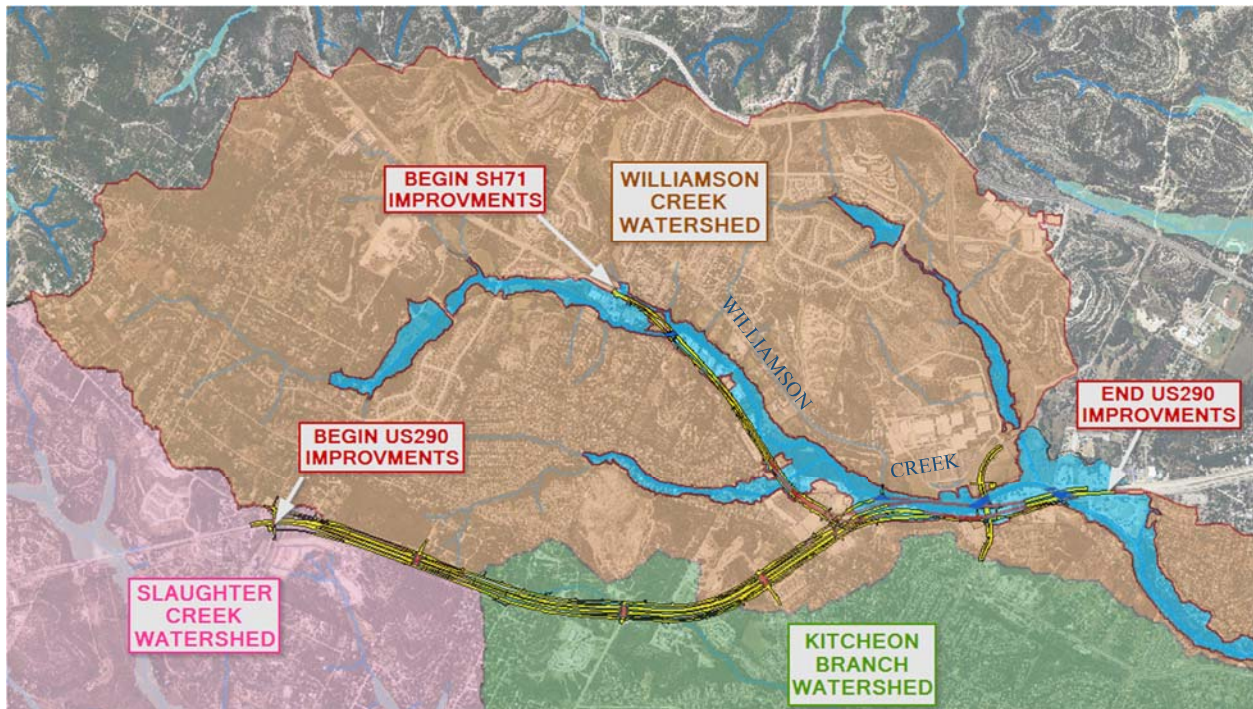

Figure 1 - Project Location

1.2 Existing Structures

The main crossing of US 290 over Williamson Creek just east of McCarty Lane consists of a 120 foot long bridge with 6 - 20 foot spans. Another crossing within the project area occurs at William Cannon Blvd and consists of a 120 foot bridge with 4 - 30 foot spans. Currently Old Bee Cave Road also crosses Williamson Creek as a low water crossing with a 6 foot by 2 foot concrete box culvert. Approximately one mile north of the US 290/SH 71 interchange, SH 71 crosses Williamson Creek just south of Silvermine Drive. This bridge consists of 4 - 25 foot spans with a total length of 100 feet.

Figure 2 - Existing Bridge Locations (US 290 & William Cannon Drive – Williamson Creek crossings)

Figure 3 - Existing Structure Location (Old Bee Cave low-water Williamson Creek crossing)

Figure 4 - Existing Bridge Location (SH 71 - Williamson Creek crossing)

1.3 Proposed Designs

Throughout the development of this project, multiple improvement concepts have been considered. The two remaining concepts for consideration are referred to as Concept A and Concept C. The major differences between these concepts are the design approaches to the US 290/SH 71 interchange. Concept A shifts both the westbound frontage road and the westbound main lanes to the north bank of Williamson Creek. The west bound main lanes are elevated throughout the creek bank area while the westbound frontage roads are mostly on grade and only elevated in places with close proximity to the bank. The eastbound main lanes are elevated and remain on the south bank, while the eastbound frontage road is on grade and maintains a fairly similar alignment to the existing highway.

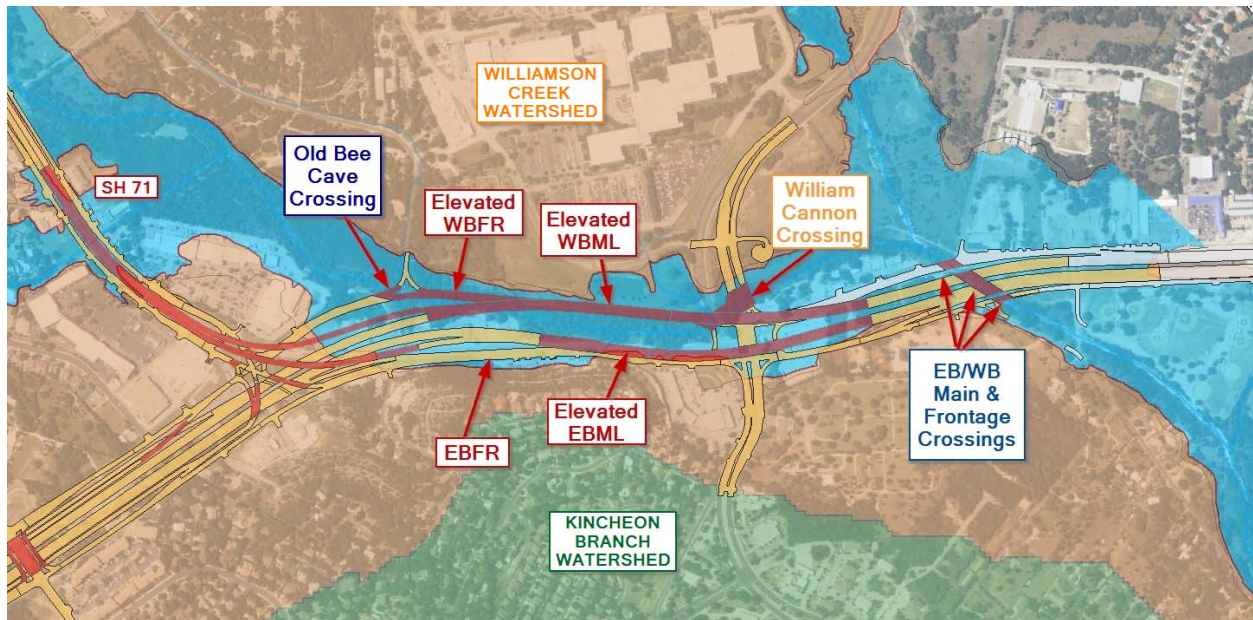

Figure 5 - Concept A Plan View

Concept C consists of west and eastbound frontage roads that follow a footprint similar to that of the existing US 290 highway, while the proposed main lanes would be elevated starting just west of the interchange and extend across the entire creek impact area returning to grade just west of Joe Tanner, effectively eliminating most all hydraulic impact of the new lane construction.

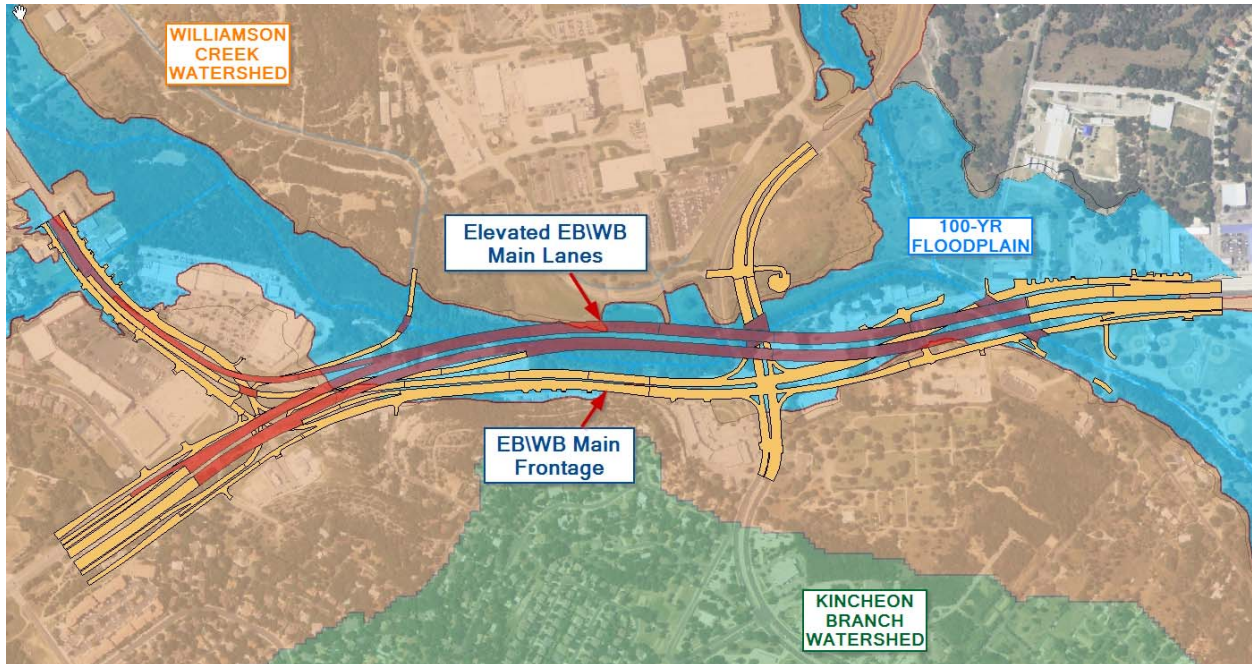

Figure 6 - Concept C Plan View

Although both concepts would have similar increased impervious area impacts on the existing watershed, Concept C would have significantly less impact due to the main lane additions being elevated throughout the impact area along Williamson Creek. Therefore, the project team determined that only Concept A would be further analyzed for its potential hydraulic impact on the creek and its watershed.

2 Hydrologic Analysis

2.1 Overview

In the February 2014 technical memo, HHR outlined our initial hydrologic analysis of the two proposed detention sites as well as the proposed impervious of both the Concept A and Concept C designs. The memo identifies and defines two off-site detention areas. The first proposed detention basin site (hereafter referred to as the OBC site) is located west of Old Bee Cave Rd and just north of Fletcher Lane.

Figure 7 - OBC Detention Site - Location Map

The second proposed detention basin (hereafter referred to as the SH 71 site) is located along the west side of SH 71 just north of Covered Bridge Drive.

Figure 8 - SH 71 Detention Site - Location Map

The Feb-2014 HHR memo further analyzed the two design concepts with various off-site detention scenarios evaluating the impact of each site individually and jointly. Results were reported at junction JWCR1050 which is located downstream of the US 290 crossing of Williamson Creek, and at junction JWCR1040, adjacent downstream of JWCR1050, since this location included inflow from all sub-basins impacted by added impervious area from the two concepts. The results from that initial evaluation are outlined in the table below.

Location	Concept	Scenario	Event	Revised Exist Q (cfs)	Prop Q (w/o detention) (cfs)	Prop Q (w/detention) (cfs)	% Change (btwn Rev Exist & Prop w/det)
JWCR1040	A	BOTH	100-Yr	11587	11601	9971	-14%

JWCR1050	C	OBC	100-Yr	11159	11170	10520	-6%
JWCR1050	C	OBC	25-Yr	7429	7447	6961	-6%

Table 1 - Initial Flow Reduction Results (February 2014 - HHR)

It was also decided that the Concept A design will ultimately have more potential stream and floodplain impacts on Williamson Creek than Concept C. It was determined, in later hydraulic analysis (June-2014 HHR), that to adequately mitigate the impervious impact of either design concept the implementation of both detention sites would be necessary. Therefore, all further hydraulic analysis focused on the implementation of both detention sites on the Concept A design alone. No other additional flow or design scenarios were further analyzed.

2.2 Existing Conditions

The Williamson Creek watershed is located in the south/southwest portion of the City of Austin. The project area is located primarily within this watershed, with small portions of the project area to the west found within the Slaughter Creek watershed, and project areas to the east in the Barton Creek watershed. HHR obtained the 2007 Effective FEMA HEC-HMS model for the Williamson Creek drainage from the City of Austin. This model included the entire Williamson Creek watershed which consists of 81 sub-basins. Of those 81 sub-basins, 18 are upstream of the proposed US 290 / SH 71 improvements.

2.3 Revised Existing Conditions

Modifications to the existing conditions model were made in order to better analyze the two proposed offsite detention sites. The OBC site lies in the WCR30W30 sub-basin. Similar to the approach of the 2007 HDR study, the WCR30W30 sub-basin, was divided into two sub-basins (WCR30W30_US and WCR30W30_DS.) These new sub-basins represent the upstream area that will drain into the proposed detention basin at the OBC site, and the area downstream of the proposed detention basin. The curve number, percent impervious, Snyder lag times, and channel cross-section shape were identical to those used in the 2007 study. HHR assessed these parameters as still representative of current conditions. Slight modifications in sub-basin area, and routing reach length and slope were made based on more current information. The SH 71 site is located in sub-basin WCR10W10. Because the proposed detention basin for the SH 71 site occurs so close to the downstream outlet of WCR10W10, it was decided that sub-dividing that basin and additional flow routing would be unnecessary.

Figure 9 - Sub-basin map of detention sites

Other revisions to the existing model included the addition of a 25-year frequency storm not previously included in the effective FEMA hydrologic model. HHR developed the 25-year frequency storm using the same initial loss rate of 1.5 inches used in the HDR 2007 study

2.4 Proposed Conditions

2.4.1 Impervious

The proposed improvements stretch across 10 sub-basins within the Williamson Creek watershed model. It was necessary to update the impervious percentage parameter for all of these sub-basins based on the impact from the proposed improvements. In order to determine the change in impervious percentage, the area of proposed impervious within the project right-of-way was compared with the existing impervious within the same right-of-way. The percent impervious set by the original FEMA model was used to determine the actual impervious area for the sub-basin. The increase in impervious area was then added and a new percent impervious calculated for each of the affected sub-basins. The following tables summarize the added impervious percentages for each of the affected sub-basins according to design concept.

Sub-Basin	Existing Percent Impervious	New Percentage
WCR1050W1100	40%	41%
WCR30W30	25%	25%
WCR50W50	35%	35%
WCR60W60	30%	31%
WCR630W720	30%	30%
WCR680W730	55%	61%
WCR690W710	20%	20%
WCR790W810	55%	56%
WCR80W80	40%	43%
WCR810W870	50%	50%

Table 2 : Concept A - Percent Impervious
 (Note: Percentages are rounded to the nearest whole number.)

2.4.2 Detention

Since the Feb-2014 HHR technical memo, further design modifications have been made to the offsite detention areas. Due changes in proposed right-of-way acquisition and other considerations associated with adjacent property access, the detention footprints and curves have been modified from the previous study. The footprints and curves were developed using the same 2012 2-ft LiDAR contour data provided by the COA as used in the previous analysis. The final OBC detention facility design parameters are outlined in the following tables.

OBC Detention Berm	
Top Berm Width	20 ft
Total Berm Length	730 LF
Berm Crest Elevation	926'
Max Berm Height (from bank)	~ 16 ft
100-YR Water Surface Elevation	925.2'
Primary Outlet	
Model Method	Culvert Outlet
Shape	Circular Concrete Pipe
Diameter	3 ft
Inlet Elevation	910'

2.4.3 Kincheon Branch Re-routing

Additional basin revisions were made to the HMS model to represent a shift of area away from Kincheon Branch. A portion of the proposed project area falls within the boundary of Kincheon Branch (a downstream tributary to Williamson Creek). Due to the nature of the proposed profile a portion of sub-basin WCR680W730 will no longer drain to Kitchen Branch, but will be captured on the project site and routed to eventual discharge near the proposed William Cannon bridge. In order to reflect this area shift, the WCR680W730 sub-basin was altered to reflect the loss of area due to improvements and sub basin WCR80W80 was altered to reflect this gain in drainage area as well.

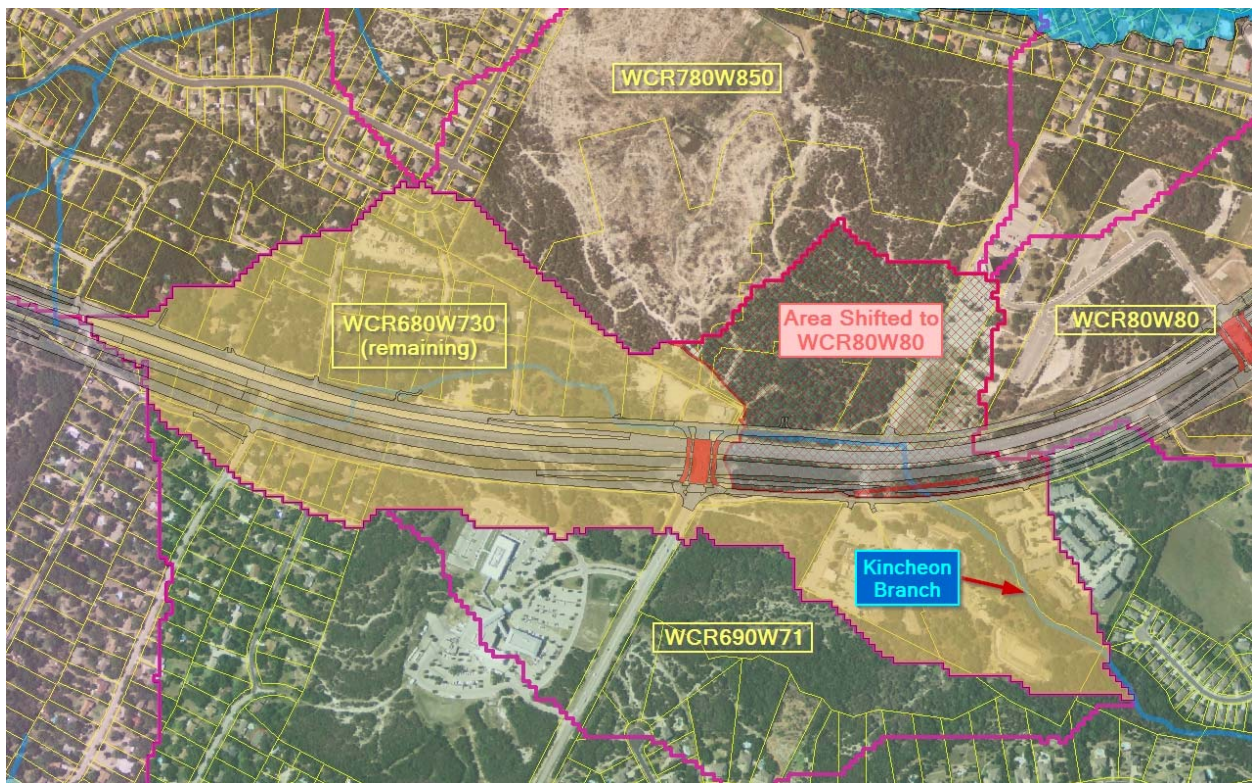

Table 8 - Kincheon Branch Area Map

New impervious calculations were made for the reduced WCR680W730 sub-basin and expanded WCR80W80 sub-basin as outlined in the table below. This area shift resulted in a modest increase in flows (1.2%-1.5%) to the discharge outlet site and an approximate 17% decrease in the WCR680W730 sub-basin flows for the 100 year frequency storm.

Sub-basin	Existing			
	Total Area	Total Area	Total Imp Area	Total Calculated % IMP
	(sq miles)	(acres)	(acres)	
WCR80W80	0.755	483.2	193.28	40.00%

2.5 HMS Model Results

In order to establish meaningful and comparable points of reference between the HMS modeling results and the HEC-RAS hydraulic model, flow change locations in the HEC-RAS model were correlated to the appropriate junction in HMS. These correlations establish more detailed points of interest within the HMS model than were analyzed in the initial hydrologic memo (Feb-2014 HHR).

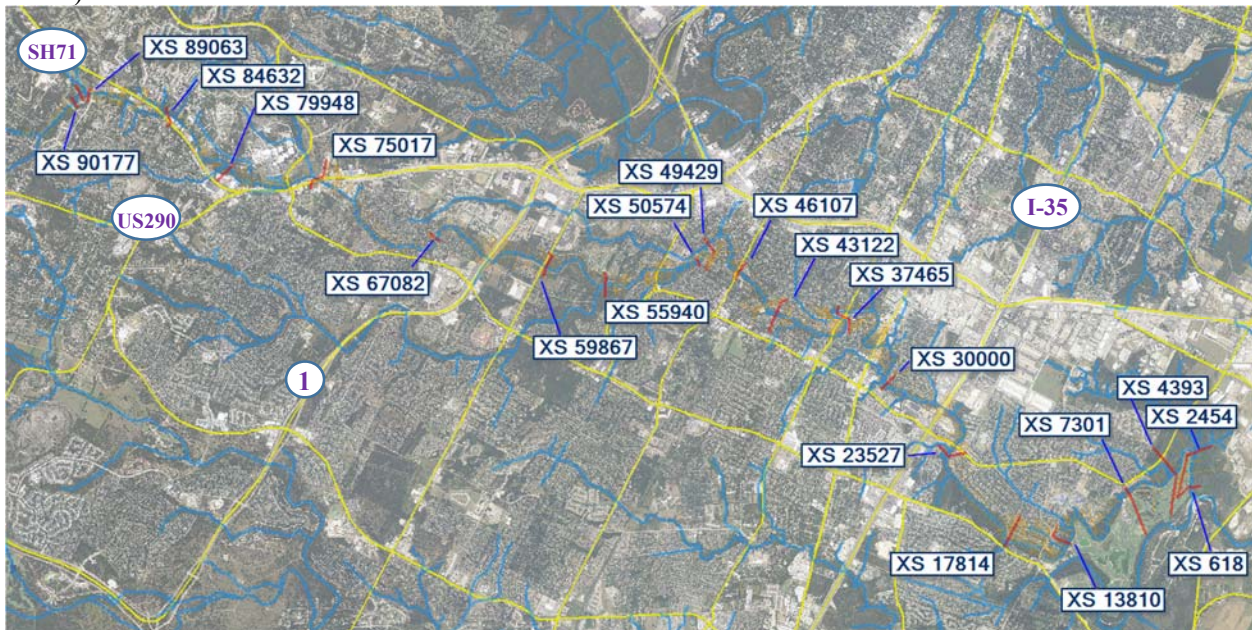

Figure 11 - HEC-RAS Cross-section Location

Using the established points of interest, the following table summarizes the results comparison between the revised existing and the proposed HMS model. The final hydrologic analysis shows average 100-year peak flow reductions ranging from 10-17% across the project area.

XS	HMS Node	Revised EXSITING			PROPOSED			Percent Change		
		10-yr	25-yr	100-yr	10-yr	25-yr	100-yr	10-yr	25-yr	100-yr

Table 11 - HMS Model Results (Concept A)

3 Hydraulic Analysis

With proposed flow conditions established, HHR further revised the hydraulic modeling in order to determine if the flow reductions and the resulting water surface elevation reductions were sufficient to mitigate the proposed improvement impacts or if further mitigation efforts would be required.

The hydraulic analysis consists of two HEC-RAS models. The first is a revised existing conditions model that updates the effective FEMA HEC-RAS model to current existing

conditions. This model is the basis for which comparisons are made with proposed conditions to assess the project impact. The second is a proposed condition model that reflects the project Concept A design; this concept has been assumed to have the most severe potential impact to flood elevations due to the “at-grade” encroachment of the alignment on the Williamson Creek floodplain. The proposed condition model will use flows developed in the hydrologic analysis representing the implementation of both detention sites, the increased impervious area, and the shifted area from Kincheon Branch sub-basin WCR680W730 to WCR80W80.

3.1 Hydraulic Modeling

3.1.1 Currently Effective Model

The current effective hydraulic model for Williamson Creek is the 2006 Williamson Creek Restudy (2006 restudy model), as provided by the City of Austin (COA). This model includes all of the Williamson Creek drainage area, starting at the confluence of Williamson Creek and Onion Creek and extends up past the proposed project site. It includes a total of three reaches and 344 cross-sections. The Manning’s n values for the main channel vary between 0.040-0.060 with an overbank variance of 0.035-0.100. This model is the foundation for developing the revised existing conditions model.

3.1.2 Revised Existing Conditions

Modifications were made to the 2006 restudy model around the project area in order to develop a revised existing conditions model. Multiple cross-sections were altered or added in the project area in order to accurately capture the conceptual crossing improvements. These additions and modifications include a new cross-section (74437) just downstream of the existing US 290 bridge, over Williamson Creek, in order to accommodate the new eastbound frontage road bridge. A new cross-section (75171.9) was added approximately 180 feet upstream of the new westbound frontage bridge in order to better model the bridge backwater transition. A new cross-section (76786) was added upstream from the existing William Cannon bridge to accommodate the expansion of that bridge. Two cross-sections (84745 and 84982) were added on either side of the existing SH 71 to reflect the conceptual widening of the crossing. All new cross-section geometry was defined using the 2012 2-ft LiDAR contour data provided by the COA and downloaded from their GIS database. The 2012 contour data was also used to compare the existing conditions model cross-sections throughout our project area. In most areas the geometry as found in the effective FEMA model appeared to be a more detailed resolution than the 2012 contour data, especially in the stream channel. However, in selected locations, the channel was modified to follow the 2012 data where it appeared to more accurately reflect conditions on the ground.

There was an issue with using the HEC-RAS flow file with the 2006 restudy model as a foundation for inserting updated detention flows to the modeling. Documentation found in the Flood Insurance Study (FIS) for the City of Austin (Revised September 26, 2008) indicates the flows generated by the HEC-HMS model provided by the City of Austin for the Onion Creek

Watershed (Williamson Creek is contained in this watershed) were not used “as-is” in the 2006 restudy HEC-RAS model. The FIS indicates that HEC-HMS flows were first input to a previous HEC-2 model that was judged to correctly estimate split flow conditions in the watershed. The split flows results were then input to the 2006 restudy FEMA model. Since HHR does not have access to the HEC-2 model or the specific procedure and process to input HEC-HMS flows into HEC-RAS model through an intermediate HEC-2 model, a revised existing flow file was created to represent flows at locations found in both the City of Austin HEC-HMS and HEC-RAS models. Moderate discrepancies resulted between flows in the revised existing model and those found in the FIS and the 2006 restudy HEC-RAS model. However, since this effort is focused on project impacts and potential mitigation based on detention, using flows directly from HEC-HMS is a representative comparison.

3.1.3 Proposed Conditions

In HHR’s initial hydraulic analysis (June-2014 HHR) preliminary bridge layouts were analyzed and determined to not meet required performance criteria. This continued hydraulic assessment determines the minimum necessary performance structures for the proposed improvements establishing low chords, span lengths and abutment designs necessary to meet the minimum design criteria. TxDOT design criteria requires that frontage roads be able to pass the 25-year event without overtopping while main lanes are required to pass the 100-year event without overtopping. HHR was provided with profile information, when available, for the proposed Concept A layout, however due to the preliminary nature of the design some assumptions were required.

Eastbound Frontage Road Bridge

The most downstream project impact is the proposed eastbound frontage road bridge. This bridge is located approximately 400 feet downstream of the existing US 290 crossing. The left abutment (west) is defined and limited by the proposed McCarty Lane intersection. The final bridge design is a total of 240 feet long with (6) forty foot spans. A 2:1 sloping abutment was assumed on the left (east) end of the bridge, however due to the limits of the intersection to the west, a vertical abutment was assumed on the right (west) end of the bridge. Additional overbank grading was required in the vicinity of the bridge in order to achieve a no impact scenario with a final low chord elevation of 809.25’.

Main Lanes Bridge

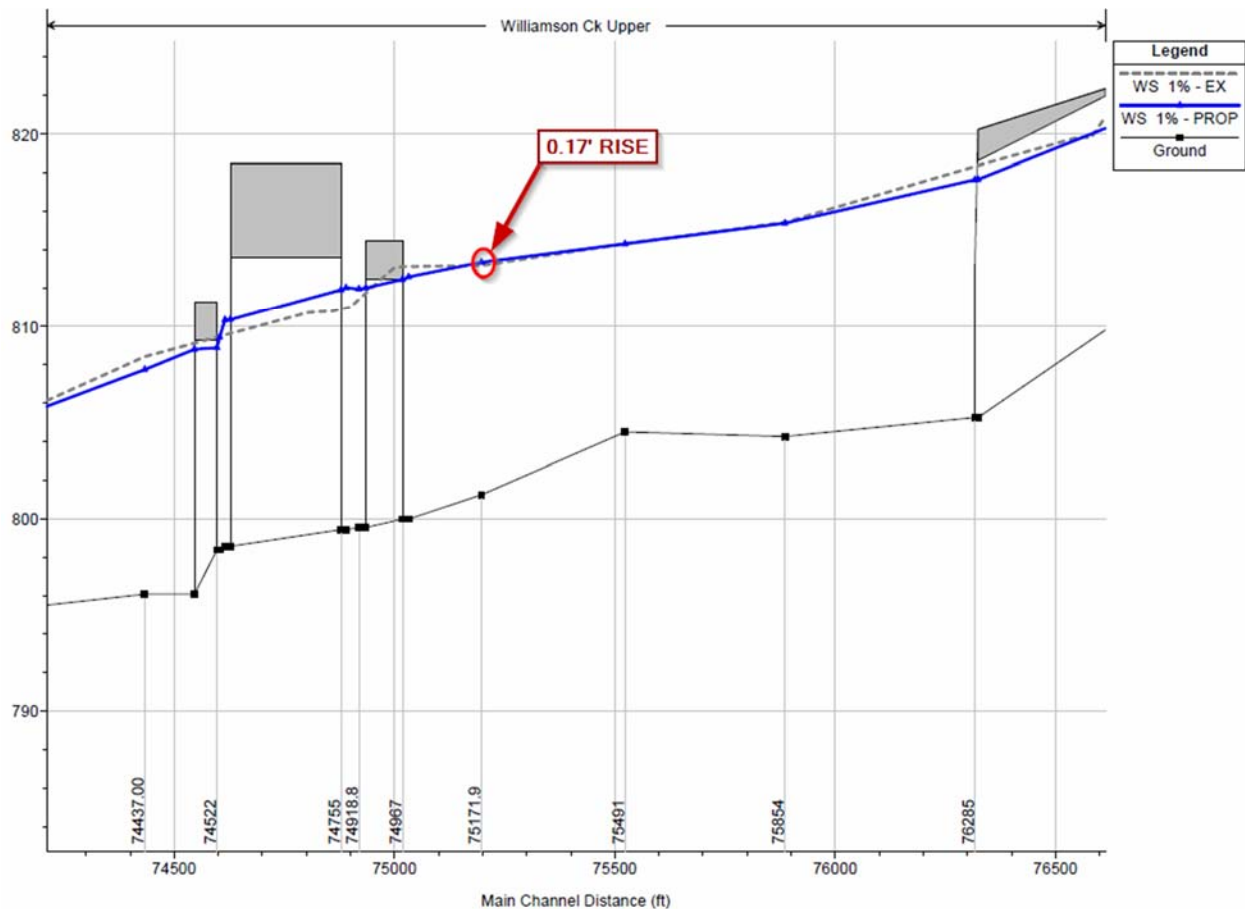

Located approximately 35 feet upstream of the proposed eastbound frontage road bridge and 30 feet downstream from the existing US 290 bridge, is the proposed main lanes bridge which will convey both east and westbound lanes as well as a portion of the eastbound on ramp. A final bridge design resulted in a 280 foot long bridge with (7) forty foot spans. Sloped abutments of 2:1 were used at both the east and west end of the bridge and additional overbank grading was

required in the vicinity of the bridge in order to achieve a no impact scenario with a final low chord elevation of 813.5'.

Westbound Frontage Road

The proposed westbound frontage road bridge will be located in approximately the same location as the existing US 290 bridge. Similar to the eastbound frontage road bridge, it is limited due to the proposed Patton Ranch Road intersection to the east and a private driveway access the west. A final bridge design of 200 feet with (5) forty foot spans was required to achieve the performance criteria. Side slope abutments at 2:1, as well as more expansive overbank grading upstream of the grouped crossings was required to maintain no impact criteria with a final low chord elevation of 812.5'.

Despite additional overbank grading, HHR was unable to achieve the strict no impact scenario at a single cross-section. At HEC-RAS cross-section 75171.9 the 100-year water surface level rises 0.17' feet above the existing profile.

HHR tested various options of additional bridge expansion and extensive grading scenarios. No solution resulted in a strict no impact result for this cross-section. However, we believe that with more detailed survey of the banks and channel, this anomalous impact section can be resolved in final project design.

William Cannon Drive Bridge

The existing bridge at William Cannon Drive will be replaced by a significantly expanded proposed bridge. The proposed structure will extend an additional 72 feet upstream of the existing bridge face and an additional 240 downstream. It will convey the widened and realigned William Cannon Blvd as well as portions of the westbound frontage road and a portion of the eastbound frontage road turnaround. Preliminary designs only included a partially developed profile for the improved William Cannon intersection. A proposed bridge profile was projected based on the available profile and existing grade information. Due to the fairly large width of the proposed structure, HHR also assumed a typical cross-slope of 2% in order to establish the upstream and downstream low chords. The final proposed bridge is a total length of 160 feet with (4) forty foot spans. Abutment slopes of 2:1 were used on both north and south ends of the bridge. Additional overbank grading was required to achieve performance criteria with a proposed downstream low chord elevation of 818.48' and a proposed upstream low chord elevation of 822.37'.

Westbound Main Lanes Flyover

The Concept A design calls for a shift of the westbound main lanes to the north bank. The resulting main lane flyover structure is proposed just east of the Old Bee Cave crossing. Due to the preliminary nature of the design and significant proposed freeboard between the water surface and the low chord, the flyover was modeled as representative pier obstruction rather than a standard bridge layout. A 2-column bent, assuming 10ft by 10ft piers, was provided by the design team as typical for a structure of this configuration and was applied to cross-section 78181 of the proposed HEC-RAS model. This cross-section also includes representative obstruction on the left (north) bank accounting for the elevated section of the westbound frontage road, as well as obstructions on the right bank (south) reflecting the eastbound main lanes and eastbound frontage road. Additional overbank grading was also applied to this section to mitigate the impact of the pier obstruction.

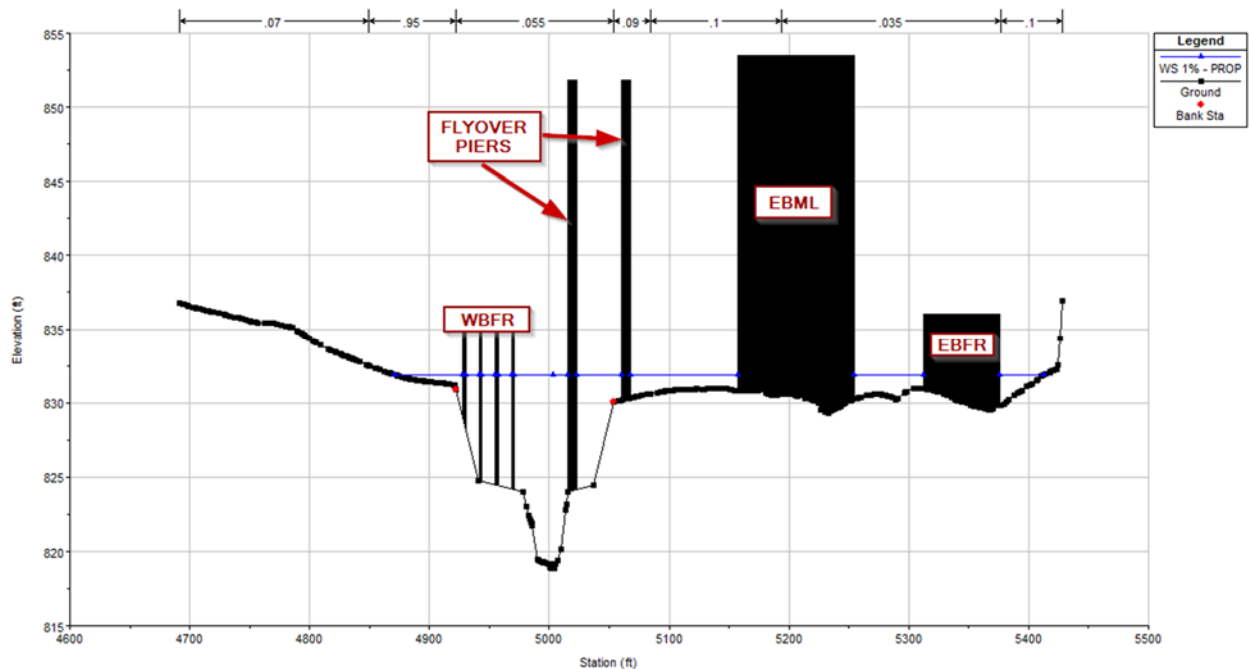

Figure 12 - Westbound Main Lanes Flyover

Old Bee Cave Road Bridge

The Concept A design calls for the removal of the existing Old Bee Cave Road low water crossing and replacement with a bridge. During preliminary design, approach road profiles were not yet defined and HHR assumed an initial profile based on the adjacent main lane profile and the existing grade. Other considerations for this crossing included obstructions representative of the blended elevated westbound frontage road structure. The final bridge design calls for a 135 foot bridge with (3) forty-five foot spans. Abutment slopes of 2:1 were assumed and additional overbank grading was applied in the bridge vicinity with a final upstream low chord elevation of 838.30' and a downstream low chord of 837.41'. The original low water crossing at this location has resulted in an exaggerated upstream sedimentation, resulting in a significant grade break in the channel slope through this crossing.

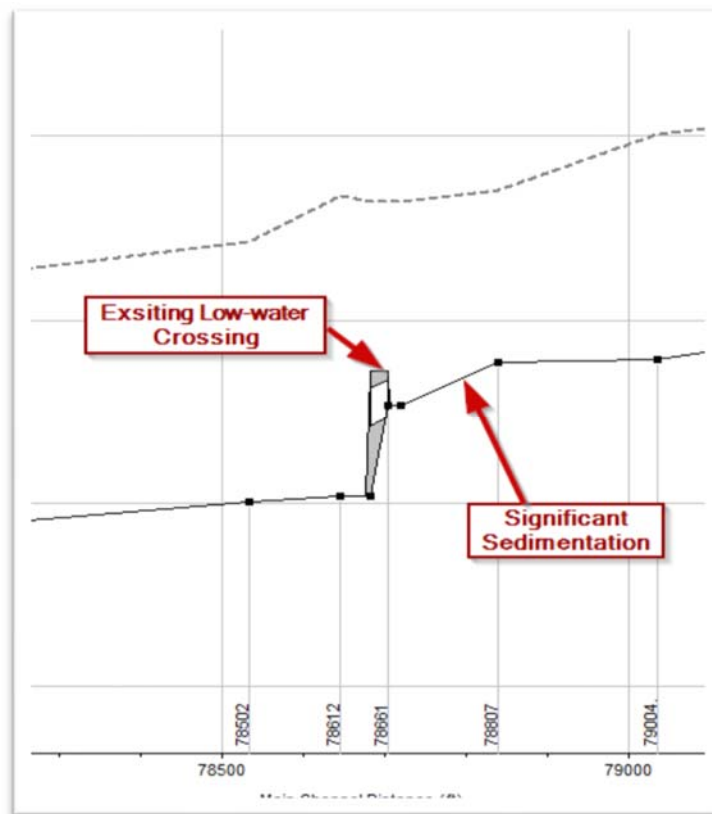

Figure 13 - OBC - Existing Stream Profile

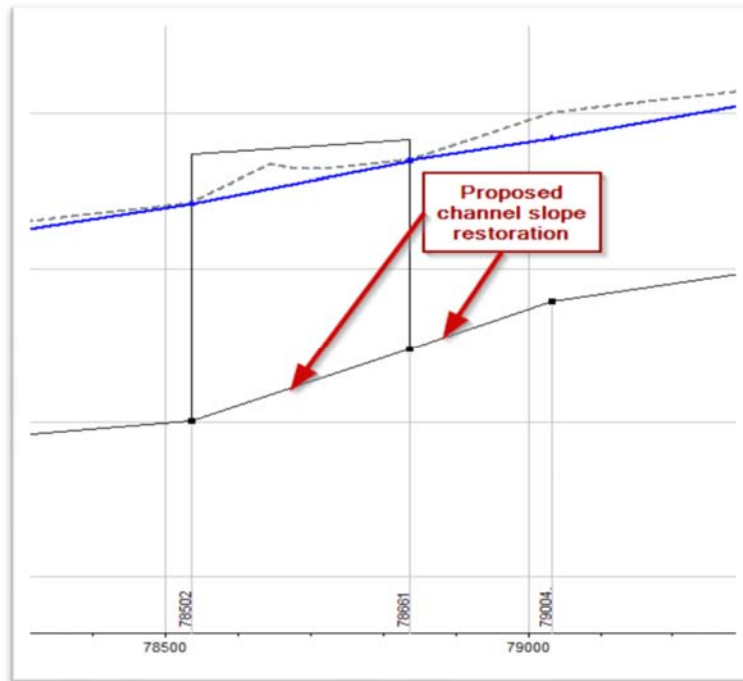

Figure 14 - OBC - Proposed Stream Profile

The proposed improvements will require that a more natural stream thalweg be established to maintain stable stream channel geometry and provide for a feasible bridge structure. A channel slope was assumed by projecting a slope between the channel bottom of upstream cross-section 79004 down to the channel bottom of cross-section 78502.

State Highway 71 Bridge

The proposed SH 71 alignment crossing calls for two individual stream crossings: one for the northbound lanes and one for southbound lanes. The existing bridge adequately conveys the 100 year storm and no profile changes were proposed for this section of the highway. Since both proposed bridges are of similar geometry and no major changes to this crossing are proposed, the crossing was modeled as a simple expansion, treating the proposed bridges as one crossing. The profile, low chords, and span arrangements were not altered from the existing bridge model. The crossing was widened to accommodate both travel directions. This widened structure conveys the 100-year flow, and no overbank adjustments or further mitigations are required.

Overbank Obstructions

Additional overbank obstructions were applied throughout the proposed HEC-RAS model in order to model the impact of proposed profile changes in the adjacent roadway. These obstructions appear in the right and left overbanks of cross-sections in the area where there are proposed roadway profile changes. The obstructions represent either the roadway fill associated

with the new structure or the straddle support structures that will be used to elevate main lanes in various places along the corridor.

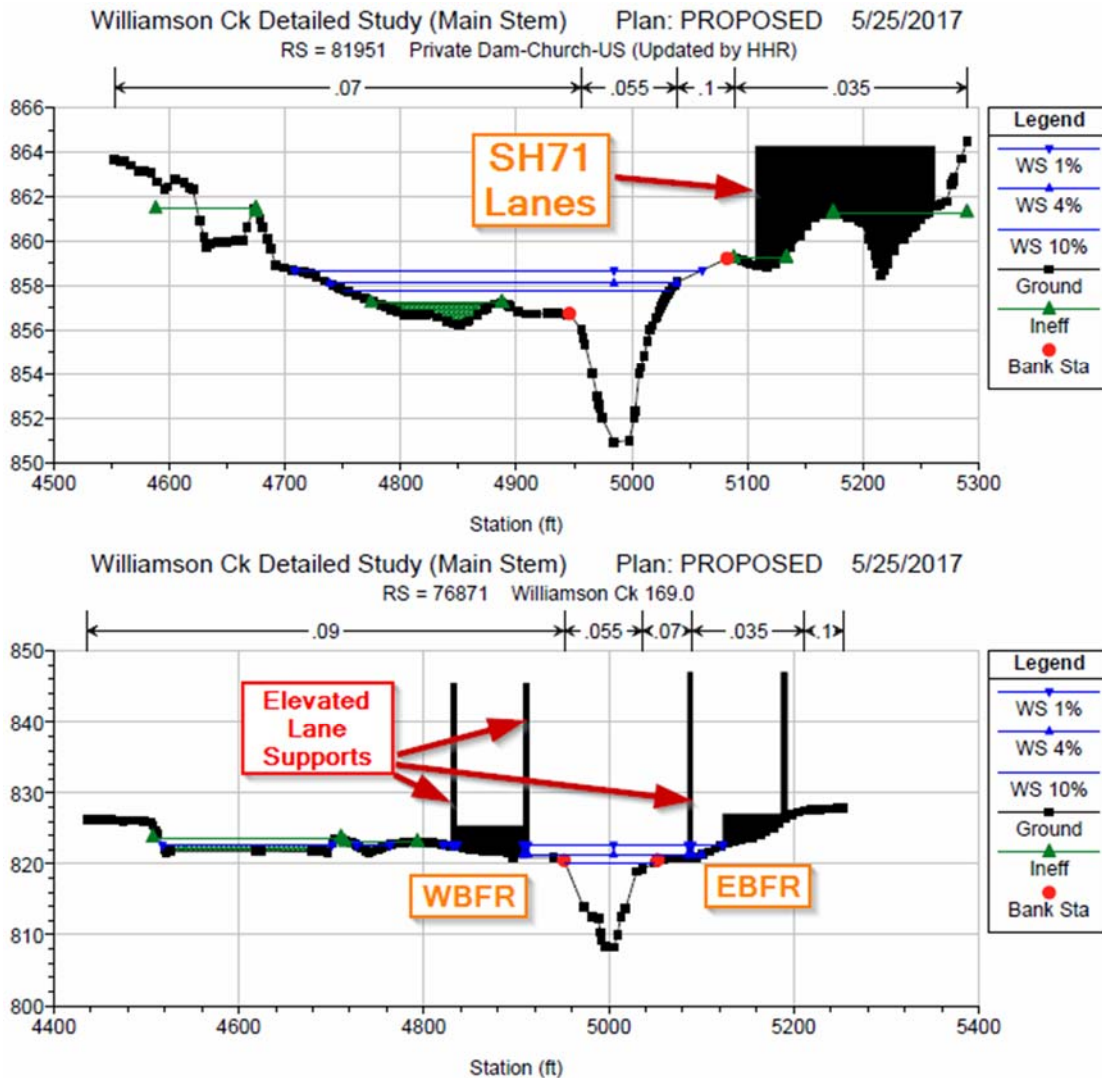

Figure 15 - Overbank Obstruction Examples

Overbank Mitigation

Overbank mitigations are recommended at six of the seven proposed stream crossings. Those mitigations follow some basic assumptions: the beginning of the mitigation at the bank is approximately 5 feet above the channel bottom, and the overbank grading is designed to maintain a 2% or greater slope to maintain proper drainage to the channel.

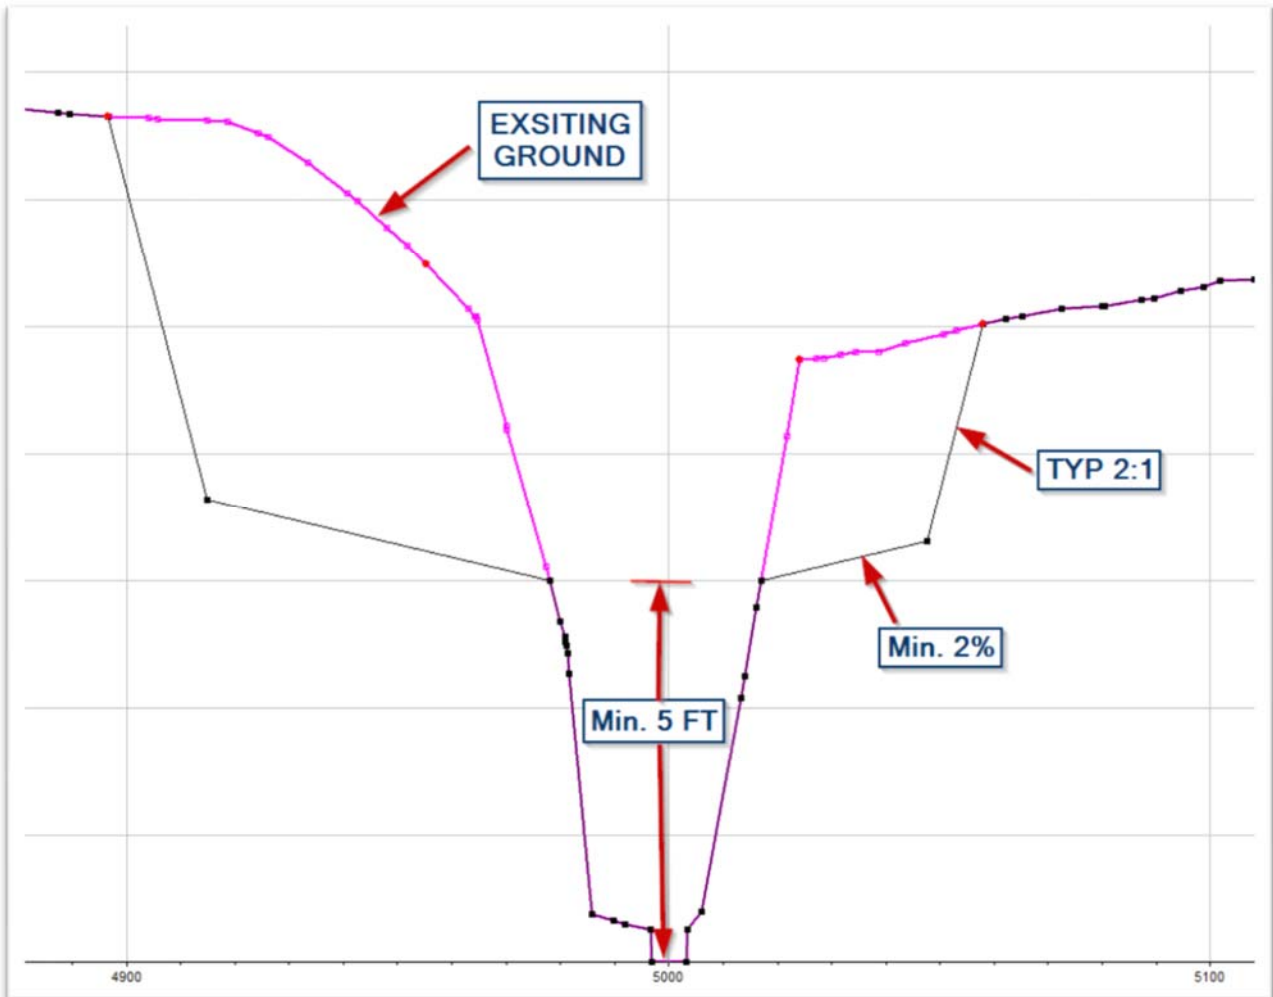

Figure 16 - Overbank Mitigation Example

Main Lanes Berm

HHR also modeled a levee in cross-section 79004 and 78807 south of the Old Bee Cave crossing. The proposed profile for the eastbound main lanes depresses between stations 359+00 and 362+25 in order to accommodate elevated frontage road crossings. It was believed that this

might result in flooding of the main lanes during a low frequency storm event, so a berm was developed as a mitigation recommendation. The berm has a maximum height of approximately 2.5 ft and was modeled in HEC-RAS as a simple levee.

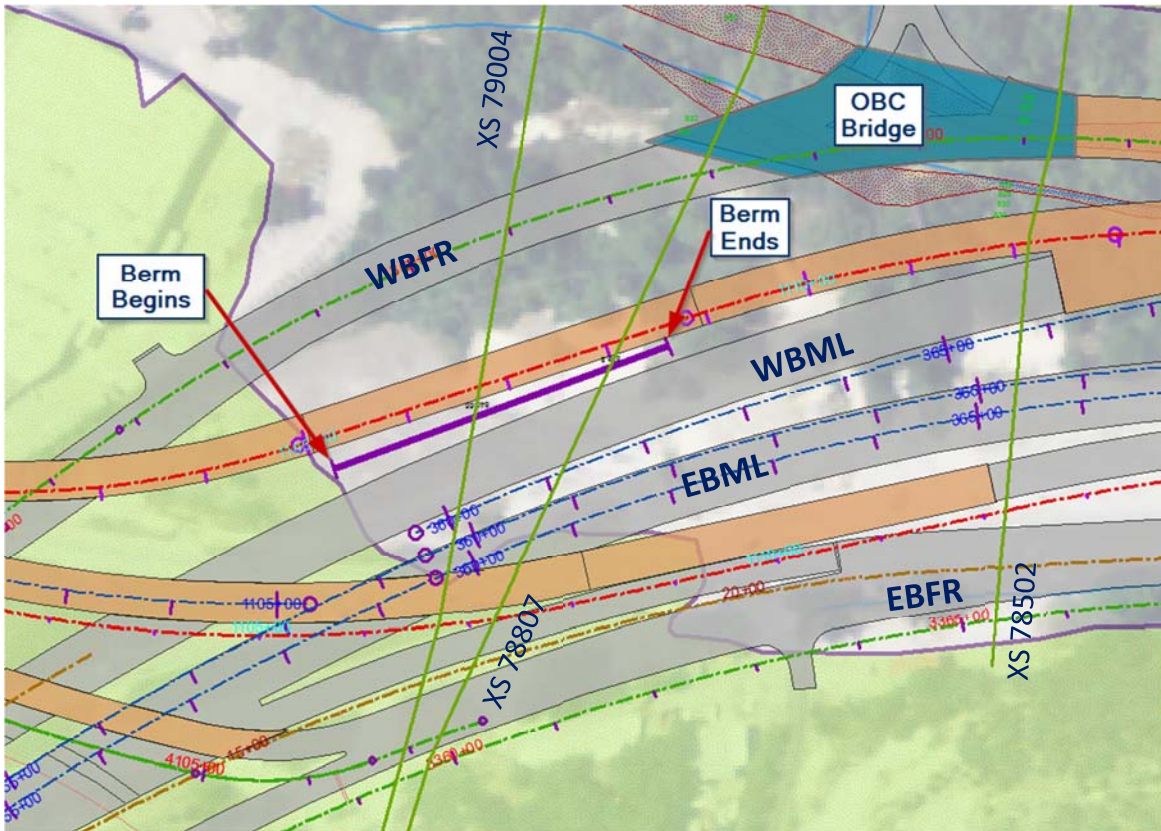

Figure 17 - Berm Plan View

4 Conclusions and Recommendations

The goal of this study was to determine the hydrologic and hydraulic impacts of the proposed Oakhill Parkway project.

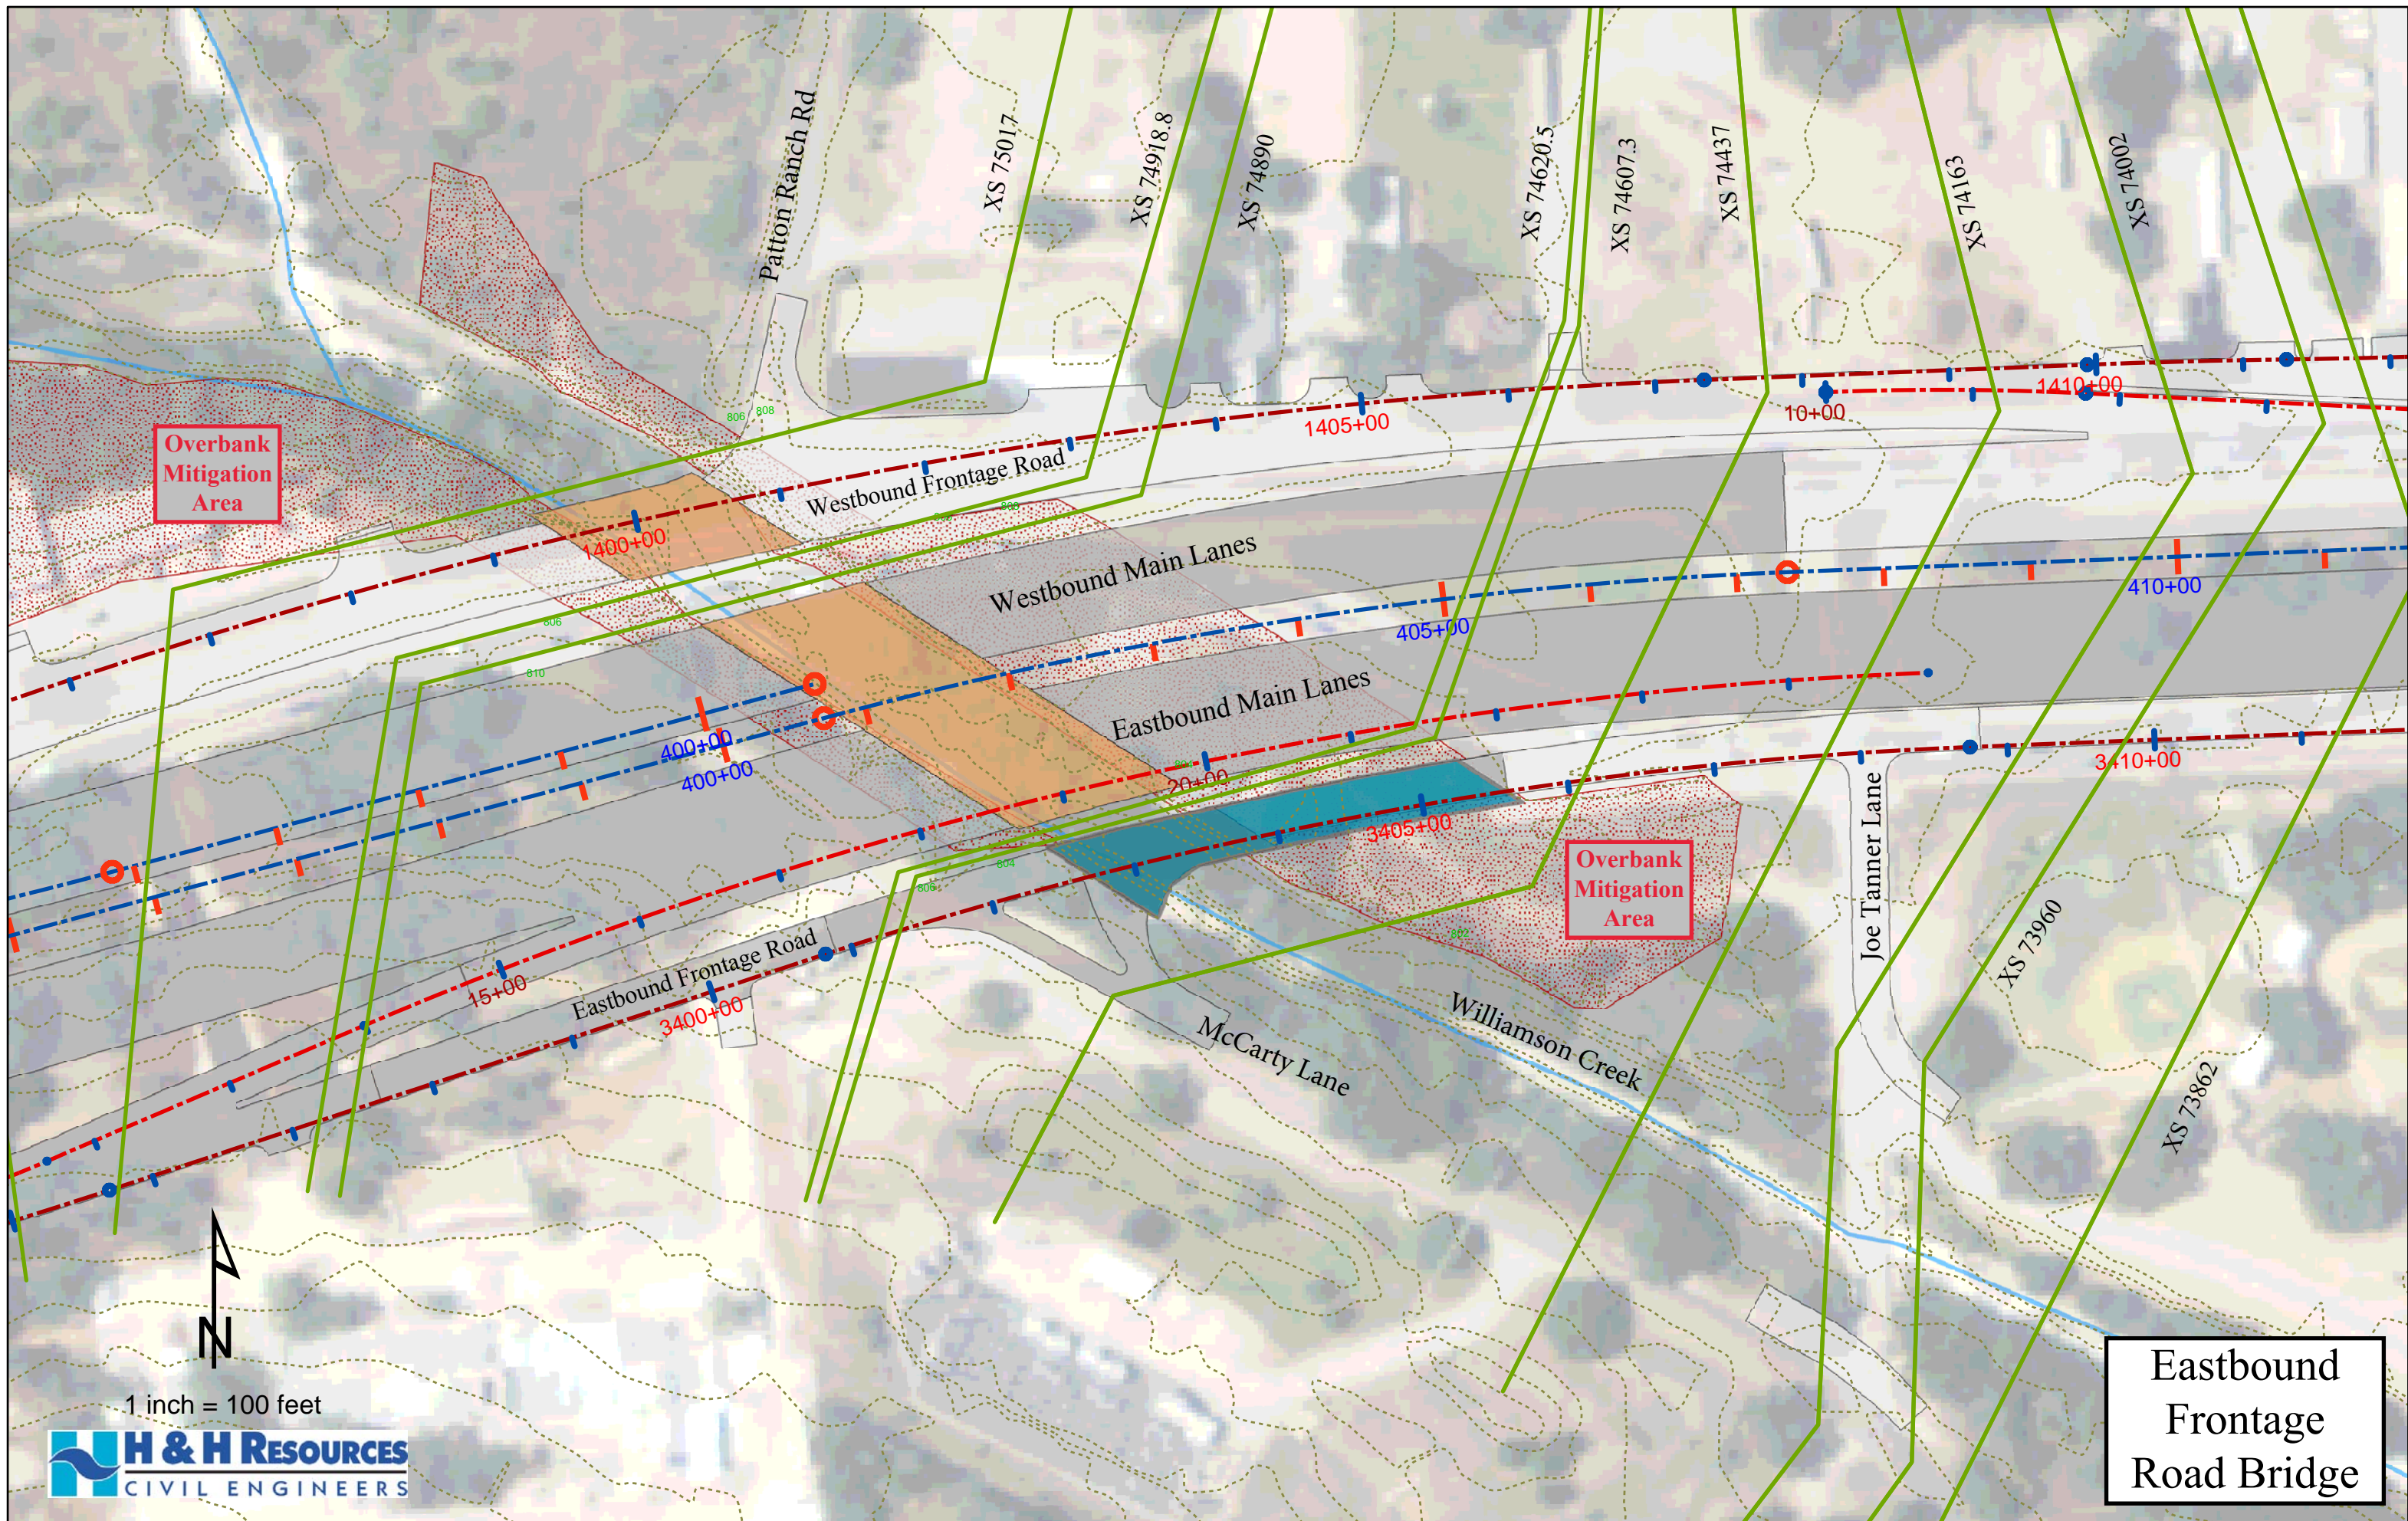

The Old Bee Cave site and SH 71 site are two detention sites, proposed for the project, to help mitigate the increased impervious and floodplain encroachment impacts. These sites were analyzed with design layouts that will contain the 100-year frequency storm while reducing the downstream flows. It was also determined that due to a shift of area from offsite flow to onsite flow, in the headwaters of Kincheon Branch, flows in that branch will be reduced by

approximately 17%. Ultimately the proposed analysis reports a 9%-10% reduction of flows across the proposed US 290/SH 71 interchange area.

The proposed Oakhill Parkway Concept A design includes 7 major stream crossings: the US 290 eastbound frontage road bridge, the US 290 main lanes bridge, the US 290 westbound frontage road bridge, the William Cannon Drive bridge, the US 290 westbound main lane flyover, the Old Bee Cave road bridge, and the SH 71 Bridge. The crossings were analyzed and proposed bridge lengths, spans, and low chords have been established for all of the crossings that allow for the conveyance of the 100 year frequency storm without overtopping. In order to achieve this conveyance and also mitigate impact to the 100-year floodplain, overbank mitigations have been proposed for all crossings except the SH 71 bridge. A 325 foot long berm is also proposed along a depressed section of the US 290 main lanes in order to ensure the lanes remain serviceable during a storm event.

Despite numerous design scenarios, a minor rise of 0.17 feet in cross-section 75171.9 was not mitigated. This section occurs just upstream of the group crossings of US 290 east and westbound frontage roads and main lanes. It is recommended that detailed survey of the channel and overbank topography be conducted prior to final design in order to establish if further mitigation is necessary in this area.
